

Phased e2e Process

PHI-free email rule - Emails are notification only, action happens in the portal. The open upload channel staying available is also right — don't close a working path just because you're adding a structured one. And the timeline at the head of the stepper is a good idea that serves double duty: it sets expectations for referral sources and becomes the skeleton of your SOP for admissions.

About the chart:

The dashed loop on the right side of Phase 5 is the "request additional" path — it routes back up to Phase 2's document request action, which fires another Resend notification. That loop can repeat as many times as the case requires without creating a new referral record.

The two new stack additions are badged in coral — the token page (`/r/[token]`) and Docuseal. Resend is marked as existing since it's already in your integrations. Everything else runs on what you've already built.

The ink signature fallback (upload manually) feeds directly into Phase 5 alongside the Docuseal path — both paths converge at bundle review, so admissions doesn't need to care which method the signer used.

Step 7. Inside the modal, admissions uses the Request Documents action. A checklist is pre-populated based on what the source marked as in custody or can obtain. Staff select what is actually needed for this case, decide whether an ROI is required, set an optional due date, write a short message, and send.

Step 8. If an ROI is required, a token link is generated simultaneously with a DOB gate enabled. That link is included in the outbound communication.

Step 9. Resend fires a single notification email to the referral source. The email contains no PHI — subject line reads "Referral MON-XXXX needs your attention." All action happens in the portal.

Phase 3 — Document Collection (Referral Source)

Step 10. The referral source receives the notification and opens their portal. They see a Documents Requested section on their referral card. Each requested item shows its status and the appropriate action — an upload field for standard documents or a signing link for the ROI.

Step 11. For standard documents, they upload the file. It attaches automatically to the referral in the admissions dashboard. The open upload link remains available at all times from the portal for any document at any point in the lifecycle.

Step 12. For the ROI, they choose one of two paths: sign now via the embedded Docuseal session, or upload a manually signed ink copy. If the signer is a third party — client, attorney, guardian — the referral source can forward the token link directly from the portal.

Phase 4 — ROI Signing (Signer)

Step 13. The signer clicks the token link and lands on `/r/[token]`. No login is required. If the DOB gate is enabled they enter the client's date of birth to proceed. An incorrect entry blocks access.

Step 14. The Docuseal signing session loads embedded on the page. The signer completes the ROI — all sections, initials, and signature — within the page. Docuseal generates a tamper-evident audit trail on completion.

Step 15. Docuseal fires a webhook to a Supabase Edge Function. The function downloads the completed PDF, stores it under `referrals/{id}/roi/` in Supabase Storage, updates the ROI section status to verified, writes an entry to the activity log, and triggers a notification to the referral source and admissions staff.

Phase 5 — Bundle Review (Admissions Staff)

Step 16. Admissions sees document statuses update in real time inside the referral modal via Supabase's realtime subscription. No refresh needed.

Step 17. For each document received, admissions can verify it, waive it with a documented reason, or flag it as insufficient and request a replacement.

Step 18. If something new surfaces mid-review that was not in the original request, admissions uses Request Additional Documents. This creates new document request records and fires a separate notification email so the referral source knows it is a new ask distinct from the original bundle.

Step 19. The additional request loop can repeat as many times as the case requires. Each round is tracked independently in the document request records with its own timestamp, requestor, and resolution status.

Phase 6 — Decision and Closure (Admissions Staff)

Step 20. When the bundle is sufficiently complete, admissions renders a decision. Status moves to accepted, waitlisted, or declined.

Step 21. A notification fires to the referral source. Email reads "Referral MON-XXXX has been updated" — no outcome details in the email. Outcome is visible in the portal.

Step 22. If accepted, admissions exports the referral to Ritten via the CSV export mapped to Ritten's intake fields. The referral record remains in the dashboard and is not deleted.

Step 23. If waitlisted, the referral remains in the active queue. Admissions can re-open review and move to accepted or declined at any point.

Step 24. If declined, the record is archived. The referral source sees the updated status in their portal.

Legend: ■ Admissions action ■ Decision point ■ New tech added

The dashed loop on both charts represents the additional document request cycle — it routes back to the notification step on the source side and the request action on the admissions side. The loop is intentionally lightweight in both charts because it can repeat without ceremony.

The Docuseal webhook is the only fully automated step in either chart — everything else requires a human action. That's intentional and worth preserving. Automation that runs without a human touchpoint in a HIPAA-governed clinical intake workflow needs to be deliberate and auditable, not convenient.

The messaging component doesn't appear as a step in either chart because it's ambient — available at every phase, not a phase itself. I noted it in the admissions chart footer for that reason.
